1 Introduction

This article introduces usage of the **LMGene** package. **LMGene** has been developed mainly for analysis of microarray data using a linear model and glog data transformation in the R statistical package.

2 Data preparation

LMGene takes objects of class **exprSet**, which is the standard data structure of the **Biobase** package. Hence, if data which is **exprSet** class is ready, the user can jump to further steps, like diagnostic plotting or g-log transformation. Otherwise, the user needs to generate new **exprSet** class data. For more detail, please see the vignette, ‘Textual Description of Biobase’ in the **Biobase** package. **Note: exprSet.** In this package, an object of **exprSet** class must contain **exprs** and **phenoData** slots with proper data.

Example. **LMGene** includes a sample array data which is of class **exprSet**. Let’s take a look this sample data.

1. First, load the necessary packages in your R session.

```
> library(LMGene)
```

```
Loading required package: Biobase
Loading required package: multtest
Loading required package: survival
Loading required package: splines
Loading required package: survival
```

```
> library(Biobase)
> library(tools)
```

2. Load the sample `exprSet` class data in the package `LMGene`.

```
> data(sample.eS)
```

3. View the data structure of the sample data and the details of `exprs` and `phenoData` slots in the data.

```
> slotNames(sample.eS)
```

```
[1] "exprs"          "se.exprs"       "description"    "annotation"     "notes"
[6] "reporterInfo"  "phenoData"
```

```
> dim(sample.eS@exprs)
```

```
[1] 613 32
```

```
> sample.eS@exprs[1:3, ]
```

```

```
[1] "pData"          "varLabels"      "varMetadata"
```

Data generation. If you don't have `exprSet` class data, you need to make some. `LMGene` provides a function that can generate an object of `exprSet` class, assuming that there are array data of `matrix` class and experimental data of `list` class.

1. The package has sample array and experimental data, `sample.mat` and `vlist`.

```
> data(sample.mat)
> dim(sample.mat)

[1] 613  32

> data(vlist)
> vlist

$patient
 [1] 1 1 1 1 2 2 2 2 3 3 3 3 4 4 4 4 5 5 5 5 6 6 6 6 7 7 7 7 8 8 8 8
Levels: 1 2 3 4 5 6 7 8

$dose
 [1] 0 1 2 3 0 1 2 3 0 1 2 3 0 1 2 3 0 1 2 3 0 1 2 3 0 1 2 3 0 1 2 3
```

2. Generate `exprSet` class data using `neweS` function.

```
> test.eS <- neweS(sample.mat, vlist)
> class(test.eS)

[1] "exprSet"
attr(,"package")
[1] "Biobase"

> identical(sample.eS, test.eS)

[1] TRUE
```

c.f. If you have different types of array data, such as `RGList`, `marrayRaw`, and so on, you can convert them into `exprSet` class by using `as` method after installing `convert` package.

3 G-log transformation

1. Estimating parameters for g-log transformation. The linear model is not applied to the raw data, but to transformed and normalized data. Many people use a log transform. LMGene uses a log-like transform involving two parameters. We estimate the parameters λ and α of the generalized log transform $\log(y - \alpha + \sqrt{(y - \alpha)^2 + \lambda}) = \sinh^{-1}(\frac{y - \alpha}{\lambda}) + \log(\lambda)$ using the function `tranest` as follows:

```
> tranpar <- tranest(sample.eS)
> tranpar

$lambda
[1] 726.6187

$alpha
[1] 56.02754
```

The optional parameter `ngenes` controls how many genes are used in the estimation. The default is all of them (up to 100,000), but this option allows the use of less. A typical call using this parameter would be

```
> tranpar <- tranest(sample.eS, 100)
> tranpar

$lambda
[1] 874.2464

$alpha
[1] 55.54313
```

In this case, 100 genes are chosen at random and used to estimate the transformation parameter. The routine returns a list containing values for `lambda` and `alpha`.

2. **G-log transformation.** Using the obtained two parameters, the g-log transformed expression set can be calculated as follows.

```
> trsample.eS <- transeS(sample.eS, tranpar$lambda, tranpar$alpha)
> sample.eS@exprs[1:3, 1:8]

      p1d0 p1d1 p1d2 p1d3 p2d0 p2d1 p2d2 p2d3
g1  216  149  169  113  193  172  167  168
g2  334  311  187  135  514  471  219  394
g3  398  367  351  239  712  523  356  629

> trsample.eS@exprs[1:3, 1:8]

      p1d0      p1d1      p1d2      p1d3      p2d0      p2d1      p2d2      p2d3
g1 5.779555 5.254781 5.441132 4.804638 5.627829 5.466407 5.423932 5.432568
g2 6.325217 6.239533 5.584240 5.101309 6.822052 6.723790 5.797778 6.519446
g3 6.531151 6.436654 6.384164 5.911558 7.180511 6.841453 6.400864 7.045494
```

3. **Tranest options:** `multiple alpha`, `lowessnorm`, `model`

Rather than using a single `alpha` for all samples, we can estimate a separate `alpha` for each sample. This allows for differences in chips, in sample concentration, or exposure conditions.

```
> tranparamult <- tranest(sample.eS, mult = TRUE)
> tranparamult

$lambda
[1] 689.2819

$alpha
[1] 69.67146 37.02711 54.13904 69.35728 60.33270 60.75301 71.72965
[8] 64.55506 58.63427 65.73625 48.40173 59.43778 76.34568 78.81046
```

```
[15] 82.20326 96.19938 77.60070 79.48089 73.63257 73.41650 33.86029
[22] 69.26448 55.75460 54.29840 139.89493 91.36521 46.46158 59.02056
[29] 73.60255 89.48728 57.13887 64.98866
```

For vector alphas, transeS uses exactly the same syntax:

```
> trsample.eS <- transeS(sample.eS, tranparamult$lambda, tranparamult$alpha)
> trsample.eS@exprs[1:3, 1:8]
```

```
      p1d0    p1d1    p1d2    p1d3    p2d0    p2d1    p2d2    p2d3
g1 5.686954 5.424873 5.449682 4.549380 5.590642 5.418542 5.268332 5.347915
g2 6.272797 6.308464 5.592073 4.915159 6.811348 6.710929 5.693269 6.492140
g3 6.488757 6.493737 6.388361 5.832776 7.173087 6.830052 6.345199 7.029530
```

It's also possible to estimate the parameters using the more accurate lowess normalization (as opposed to uniform normalization):

```
> tranparamult <- tranest(sample.eS, ngenes = 100, mult = TRUE,
+   lowessnorm = TRUE)
> tranparamult
```

```
$lambda
[1] 655.1817
```

```
$alpha
[1] 72.33459 54.85916 59.95882 67.84961 65.76304 72.80078 74.63962
[8] 59.91484 54.35704 69.41260 71.14899 62.35461 61.59616 75.55289
[15] 59.27235 86.55559 61.67145 59.51983 63.81498 62.58284 60.05210
[22] 99.95130 58.68123 61.70271 171.23313 119.38508 57.23296 73.56054
[29] 65.25109 98.40390 67.89693 63.68758
```

It is even possible now to estimate parameters using a specified model. For example, if we think that the interaction of variables in vlist is important, we can add interaction to the model:

```
> tranpar <- tranest(sample.eS, model = "patient + dose + patient:dose")
> tranpar
```

```
$lambda
[1] 860.0836
```

```
$alpha
[1] 55.68625
```

The model is always specified in the same way as the right-hand side of an lm model. In the example above, we set the parameters to minimize the mean squared error for a regression of transformed gene expression against patient, log dose, and their interaction.

Be very careful of using interactions between factor variables. If you do not have enough replications, you can easily overfit the data and have no errors to work with.

Naturally, it's possible to use mult, lowessnorm, and model all together.

4 Finding differentially expressed genes

1. **Transformation and Normalization.** Before finding differentially expressed genes, the array data needs to be transformed and normalized.

```
> trsample.eS <- transeS(sample.eS, tranparmult$lambda, tranparmult$alpha)
> ntrsample.eS <- lnormeS(trsample.eS)
```

2. **Finding differentially expressed genes** The lmgene routine computes significant probes using the method of Rocke (2003). A typical call would be

```
> sigprobes <- LMGene(ntrsample.eS)
```

There is an optional argument, level, which is the test level, .05 by default. A call using this optional parameter would look like

```
> sigprobes <- LMGene(ntrsample.eS, level = 0.01)
```

The result is a list whose components have the names of the effects in the model. The values are the significant genes for the test of that effect or else the message "No significant genes".

As with tranest, it's possible to specify a more complex model to LMGene:

```
> sigprobes <- LMGene(ntrsample.eS, model = "patient+dose+patient:dose")
> sigprobes
```

```
$patient
 [1] "g2"  "g3"  "g9"  "g10" "g14" "g15" "g49" "g54" "g84" "g85"
[11] "g86" "g93" "g102" "g123" "g139" "g155" "g178" "g179" "g205" "g250"
[21] "g256" "g271" "g277" "g304" "g310" "g319" "g327" "g336" "g372" "g375"
[31] "g384" "g399" "g405" "g406" "g407" "g408" "g409" "g410" "g411" "g412"
[41] "g413" "g414" "g415" "g423" "g425" "g460" "g461" "g462" "g463" "g477"
[51] "g503" "g520" "g524" "g528" "g566" "g607" "g612"

$dose
[1] "No significant genes"

$`patient:dose`
[1] "No significant genes"
```

The routine LMGene requires the multtest package.
